# Function approximation by the finite element method

MATMEK-4270

Prof. Mikael Mortensen, University of Oslo

#### **Short recap**

We have considered the approximation of functions  $u(x), x \in \Omega = [a,b]$  using  $u(x) pprox u_N(x)$  and

$$u_N(x) = \sum_{i=0}^N \hat{u}_i \psi_i(x)$$

- ullet  $\psi_i(x)$  have been **global** basis functions, defined on all of  $\Omega=[a,b]$
- ullet  $\{\hat{u}_i\}_{i=0}^N$  are the unknowns

We have found  $\{\hat{u}_i\}_{i=0}^N$  using

- The least squares method (variational)
- The Galerkin method (variational)
- The Collocation method (interpolation)

### Advantages and disadvantages of the global variational methods

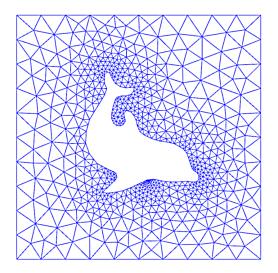

#### **Advantages**

- Spectral accuracy
- Efficient for orthogonal basis functions
- No mesh

#### Disadvantages

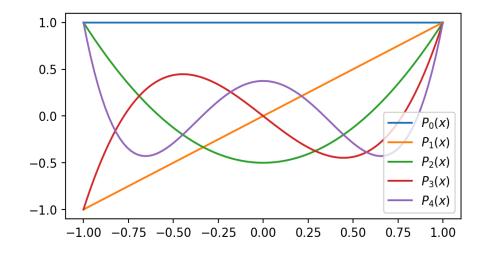

- Mainly feasible for simple domains, like lines and rectangles
- Inefficient for non-orthogonal basis functions

Impossible to use for **unstructured meshes**, like

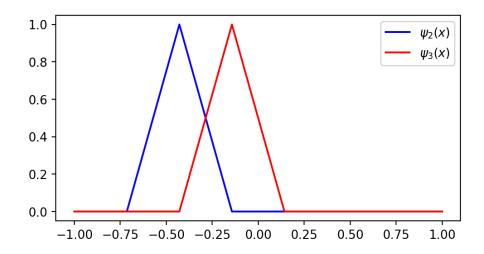

# The finite element method is a variational method using *local basis functions*

#### 5 global basis functions

2 **local** piecewise linear basis functions

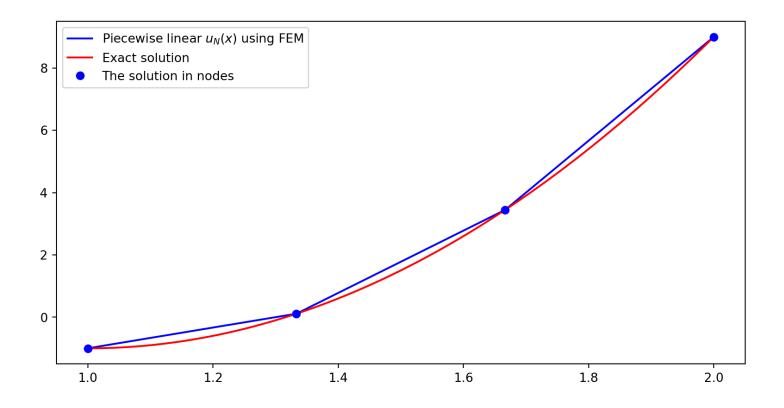

The Galerkin formulation is the same whether you use a global approach with Legendre polynomials or a local FEM with piecewise linear polynomials. The difference lies all in the function spaces and the choice of basis.

Find  $u_N \in V_N (= \operatorname{span}\{\psi_j\}_{j=0}^N)$  such that

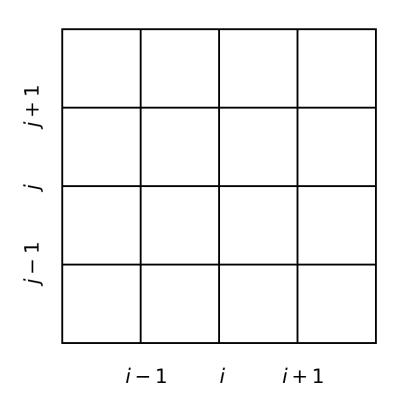

$$(u-u_N,v)=0 \quad orall \, v \in V_N$$

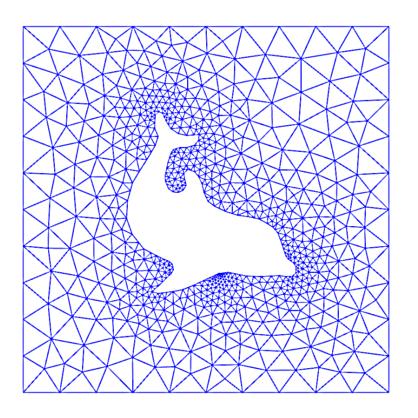

# Piecewise linear basis functions lead to piecewise linear approximations $u_N(x)$

- With FEM  $u_N(x)$  is defined everywhere in the domain  $\Omega$  and not just in mesh points.
- Interpolation is not needed since  $u_N(x) = \sum_{j=0}^N \hat{u}_j \psi_j(x), \quad x \in \Omega.$

# The finite element method is especially well suited for unstructured meshes in complex geometries Structured mesh Unstructured mesh

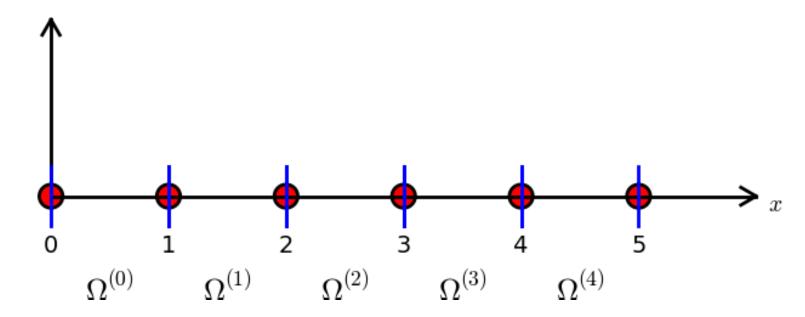

But in this course we will learn FEM using simple structured meshes.

#### The finite element mesh

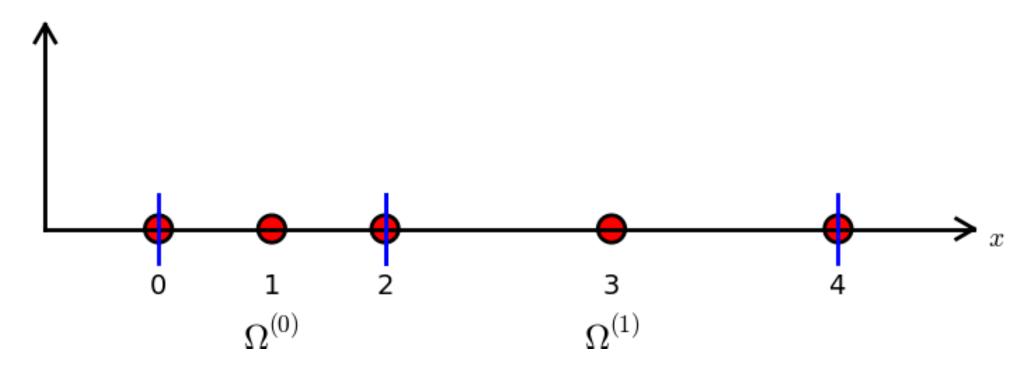

The domain  $\Omega$  is divided into  $N_e$  smaller, non-overlapping, subdomains  $\Omega^{(e)}$  , such that

$$\Omega = igcup_{e=0}^{N_e-1} \Omega^{(e)}$$

- The smaller subdomains between the blue lines are referred to as elements.
- The red dots are referred to as **nodes**, just like for interpolation methods.

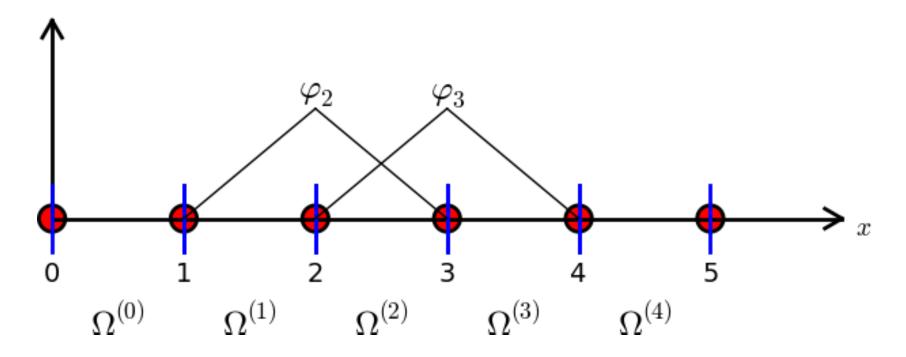

#### There may be many nodes inside each element

The figure shows a mesh with 5 non-uniform nodes and 2 non-uniform elements

Using more nodes inside each element is how the FEM can achieve higher order accuracy

#### Finite element basis functions

An element with no internal nodes can at best use piecewise linear basis functions

$$\psi_j(x) = egin{cases} rac{x-x_{j-1}}{x_j-x_{j-1}} & x \in [x_{j-1},x_j], \ rac{x-x_{j+1}}{x_j-x_{j+1}} & x \in [x_j,x_{j+1}], \ 0 & ext{otherwise}, \end{cases}$$

#### The FEM is a variational method

Use a continuous piecewise linear function space  $V_N = \operatorname{span}\{\psi_j\}_{j=0}^N$  , where

$$\psi_j(x) = egin{cases} rac{x-x_{j-1}}{x_j-x_{j-1}} & x \in [x_{j-1},x_j] \ rac{x-x_{j+1}}{x_j-x_{j+1}} & x \in [x_j,x_{j+1}] \ 0 & ext{otherwise} \end{cases}$$

To approximate a function  $u(x), x \in \Omega = [a,b]$ , we can now use the variational Galerkin method: Find  $u_N \in V_N$  such that

$$(u-u_N,v)=0 \quad orall \, v \in V_N$$

We can still use  $v=\psi_i$  and  $u_N(x)=\sum_{j=0}^N \hat{u}_j\psi_j(x)$ , exactly like for the global Galerkin method and obtain:

$$\sum_{j=0}^N (\psi_j,\psi_i) \hat{u}_j = (u,\psi_i), \quad i=0,1,\ldots,N$$

#### The element mass matrix

The mass matrix  $A=(a_{ij})_{i,j=0}^N$  is

$$a_{ij}=(\psi_j,\psi_i)=\int_\Omega \psi_j\psi_i dx, \quad (i,j)\in (0,\dots,N)^2$$

However, since each basis function is only non-zero on at most two elements, we usually assemble elementwise and add up (this works very well on unstructured meshes!)

$$a_{ij} = \sum_{e=0}^{N_e-1} a_{ij}^{(e)} = \sum_{e=0}^{N_e-1} \int_{\Omega^{(e)}} \psi_j \psi_i dx_i$$

We define the **element mass matrix**  $A^{(e)} = (a_{ij}^{(e)})_{i,j=0}^N$  as

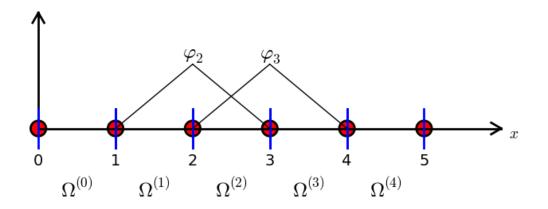

$$a_{ij}^{(e)}=\int_{\Omega^{(e)}}\psi_j\psi_idx,\quad (i,j)\in (0,\dots,N)^2$$

The finite element method is **much more difficult to implement** than global methods, because of the local basis functions and unstructured mesh. Yet, the unstructured mesh and local basis functions make the method **much more flexible**.

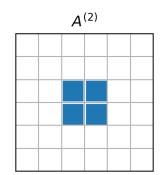

#### The element mass matrix is highly sparse

$$a_{ij}^{(e)}=\int_{\Omega^{(e)}}\psi_j\psi_i dx,$$

For piecewise linear basis functions there are only 2 non-zero basis functions per element. See element  $\Omega^{(2)}$ 

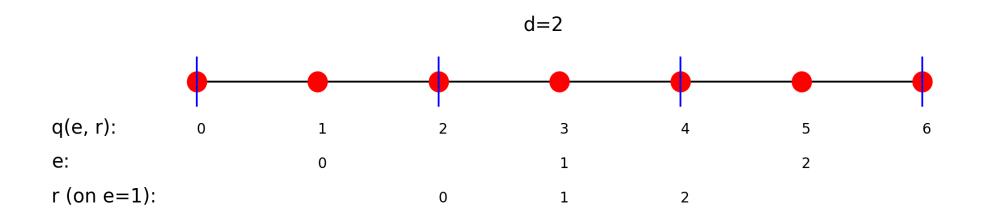

The matrix  $A^{(2)}$  will have only 4 non-zero items. So it is really a waste of memory using an (N+1) imes (N+1) matrix.

#### Define a local-to-global map q(e,r)

$$q(e,r) = de + r$$

Mapping local index  $r\in(0,\ldots,d)$  on global element e to the global index  $q(e,r)\in(0,1,\ldots,N).$  There are d+1 nodes per element.

For unstructured meshed q(e,r) needs to be stored explicitly (r numbering is implicit):

$$q = \left\{0: egin{bmatrix} 0 \ 1 \ 2 \end{bmatrix} & 1: egin{bmatrix} 2 \ 3 \ 4 \end{bmatrix} & 2: egin{bmatrix} 4 \ 5 \ 6 \end{bmatrix}
ight\}$$

#### Use a local dense element mass matrix

With d+1 nonzero basis functions on element e all the non-zero items of  $A^{(e)}$  can be stored in the dense matrix:

$$ilde{A}^{(e)} = ( ilde{a}_{rs}^{(e)})_{r,s=0}^d$$

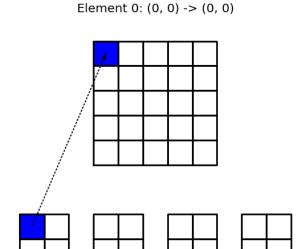

$$ilde{a}_{rs}^{(e)}=\int_{\Omega^{(e)}}\psi_{q(e,r)}\psi_{q(e,r)}dx$$

#### Note

The matrix  $\tilde{A}^{(e)}$  contains the same nonzero items as  $A^{(e)}$ , but  $\tilde{A}^{(e)} \in \mathbb{R}^{(d+1)\times(d+1)}$  is dense, whereas  $A^{(e)} \in \mathbb{R}^{(N+1)\times(N+1)}$  is highly sparse.

#### Local to global mapping in assembly of ${\cal A}$

The 4 smaller matrices represent  $ilde{A}^{(0)}, ilde{A}^{(1)}, ilde{A}^{(2)}$  and  $ilde{A}^{(3)}$ 

Finite element assembly: add up for  $e=0,1,\ldots,N_e-1$  and  $(r,s)\in(0,1,\ldots,d)^2$ 

$$a_{q(e,r),q(e,s)} += ilde{a}_{r,s}^{(e)}$$

#### Mapping to reference domain

In assembling the matrix A we need to compute the element matrix  $\tilde{A}^{(e)}$  many times. Is this really necessary? The integrals

$$\int_{\Omega^{(e)}} \psi_{q(e,r)} \psi_{q(e,s)} d\Omega,$$

differ only in the domain, whereas the **shape of the basis functions** is the same regardless of domain. The piecewise linear basis functions are always straight lines.

Let us map all elements to a reference domain  $\Omega^r=[-1,1]$ . The affine map from  $x\in\Omega^{(e)}=[x_{q(e,0)},x_{q(e,d)}]=[x_L,x_R]$  to  $X\in\Omega^r$  can be written for any element as

$$x = rac{1}{2}(x_L + x_R) + rac{1}{2}(x_R - x_L)X$$

Mapping back and forth is as usual

$$X(x)$$
 or  $x(X)$ 

#### Mapping finite element basis functions

The basis functions  $\psi_{q(e,r)}(x)$  are commonly mapped to the Lagrangian basis functions

$$\psi_{q(e,r)}(x) = \ell_r(X) = \prod_{\substack{0 \leq s \leq d \ s 
eq r}} rac{X - X_s}{X_r - X_s}$$

where

$$X_r=-1+rac{2r}{d},\quad r=0,1,\ldots,d$$

and for piecewise linear basis functions (d=1) we get the following basis functions on the reference domain:

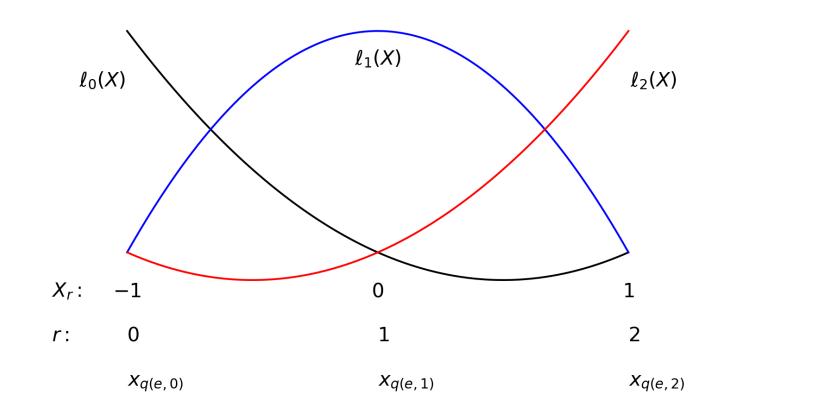

$$\ell_0(X) = rac{1}{2}(1-X) \quad ext{and} \quad \ell_1(X) = rac{1}{2}(1+X)$$

#### Quadratic elements (d=2)

For quadratic elements the Lagrange basis functions on the reference domain are

$$(X_0, X_1, X_2) = (-1, 0, 1)$$

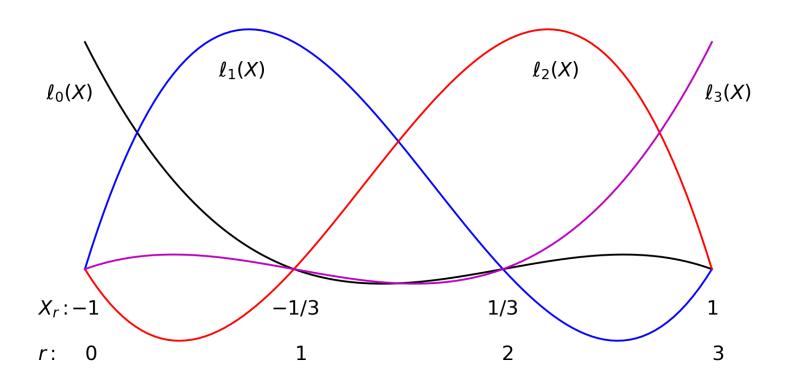

$$\ell_0(X) = rac{1}{2}X(1-X), \quad \ell_1(X) = (1-X^2), \quad \ell_2(X) = rac{1}{2}X(1+X)$$

18 / 38

#### d=3 and $(X_0,X_1,X_2,X_3)=(-1,-1/3,1/3,1)$

$$\ell_0(X) = -\frac{9}{16}(X-1)(X-\frac{1}{3})(X+\frac{1}{3}) \qquad \ell_1(X) = \frac{27}{16}(X-1)(X-\frac{1}{3})(X+1)$$
$$\ell_2(X) = -\frac{27}{16}(X-1)(X+\frac{1}{3})(X+1) \qquad \ell_3(X) = \frac{9}{16}(X-\frac{1}{3})(X+\frac{1}{3})(X+1)$$

#### Back to the element matrix

Use a change of variables (x o X and  $\psi_{q(e,r)}(x)=\ell_r(X)$ ) for the inner product:

$$egin{align} ilde{a}_{rs}^{(e)} &= \int_{\Omega^{(e)}} \psi_{q(e,r)}(x) \psi_{q(e,s)}(x) d\Omega, \ &= \int_{x_L}^{x_R} \psi_{q(e,r)}(x) \psi_{q(e,s)}(x) dx, \ &= \int_{-1}^{1} \ell_r(X) \ell_s(X) rac{dx}{dX} dX, \end{aligned}$$

where dx/dX=h(e)/2 and  $h(e)=x_{q(e,d)}-x_{q(e,0)}=x_R-x_L$ , such that for any element, regardless of order d, we can compute the elements of the element matrix as

$$ilde{a}_{rs}^{(e)} = rac{h(e)}{2} \int_{-1}^{1} \ell_r(X) \ell_s(X) dX$$

Note that the integral does not depend on element number e!

#### Since the integral does not depend on the element

then, instead of computing for each (linear) element:

$$ilde{A}^{(e)} = egin{bmatrix} \int_{\Omega^{(e)}} \psi_{q(e,0)} \psi_{q(e,0)} dx & \int_{\Omega^{(e)}} \psi_{q(e,0)} \psi_{q(e,1)} dx \ \int_{\Omega^{(e)}} \psi_{q(e,1)} \psi_{q(e,1)} dx & \int_{\Omega^{(e)}} \psi_{q(e,1)} \psi_{q(e,1)} dx \end{bmatrix}\!,$$

we can simply use:

$$ilde{A}^{(e)} = rac{h(e)}{2} egin{bmatrix} \int_{-1}^1 \ell_0 \ell_0 dX & \int_{-1}^1 \ell_0 \ell_1 dX \ \int_{-1}^1 \ell_1 \ell_0 dX & \int_{-1}^1 \ell_1 \ell_1 dX \end{bmatrix}.$$

with merely a different h(e) for each element.

Similarly for higher d.

#### Sympy implementation element mass matrix

Linear (d=1)

```
1 h = sp.Symbol('h')
2 l = Lagrangebasis([-1, 1])
3 ae = lambda r, s: sp.integrate(l[r]*l[s], (x, -1, 1))
4 A1e = h/2*sp.Matrix([[ae(0, 0), ae(0, 1)], [ae(1, 0), ae(1, 1)]])
5 A1e
```

```
\begin{bmatrix} \frac{h}{3} & \frac{h}{6} \\ \frac{h}{6} & \frac{h}{3} \end{bmatrix}
```

#### Quadratic (d=2)

```
1  l = Lagrangebasis([-1, 0, 1])
2  ae = lambda r, s: sp.integrate(l[r]*l[s], (x, -1, 1))
3  A2e = h/2*sp.Matrix(np.array([[ae(i, j) for i in range(3) for j in range(3)]]).reshape(3, 3))
4  A2e
```

$$\begin{bmatrix} \frac{2h}{15} & \frac{h}{15} & -\frac{h}{30} \\ \frac{h}{15} & \frac{8h}{15} & \frac{h}{15} \\ -\frac{h}{30} & \frac{h}{15} & \frac{2h}{15} \end{bmatrix}$$

#### Complete assembly implementation

```
Ae = [A1e, A2e] # previously computed
   def get_element_boundaries(xj, e, d=1):
       return xi[d*e], xi[d*(e+1)]
   def get_element_length(xj, e, d=1):
       xL, xR = get_element_boundaries(xj, e, d=d)
       return xR-xL
 9
   def local_to_global_map(e, r=None, d=1): # q(e, r)
11
       if r is None:
           return slice(d*e, d*(e+1)+1)
12
13
       return d*e+r
14
15
   def assemble_mass(xj, d=1):
16
       N = len(xj)-1
17
       Ne = N//d
       A = np.zeros((N+1, N+1))
18
19
       for elem in range(Ne):
20
           hj = get_element_length(xj, elem, d=d)
21
           s0 = local_to_global_map(elem, d=d)
22
           A[s0, s0] += np.array(Ae[d-1].subs(h, hj), dtype=float)
23
       return A
```

```
1 N = 4
2 xj = np.linspace(1, 2, N+1)
3 A = assemble_mass(xj, d=1)
4 print(A)

[[0.0833 0.0417 0. 0. 0. 0. ]
[[0.0417 0.1667 0.0417 0. 0. ]

```

#### Sparsity pattern:

- The internal nodes represent rows with only 3 nonzero items. The nodes on the boundary between two elements have rows containing 5 nonzero items.
- The mass matrix is not diagonal, but it is sparse.

#### Finite element assembly of a vector

In solving for

$$\sum_{j=0}^N (\psi_j,\psi_i) \hat{u}_j = (u,\psi_i), \quad i=0,1,\ldots,N$$

we also need the right hand side

$$b_i=(u,\psi_i), \quad i=0,1,\ldots,N$$

This inner product can also be evaluated **elementwise**, and mapped just like the mass matrix. We define the element vector similarly as the element matrix

$$b_i^{(e)} = \int_{\Omega^{(e)}} u(x) \psi_i(x) dx, \quad i=0,1,\ldots,N$$

 $b_i^{(e)}$  will be highly sparse.

#### Define a dense local vector

$$ilde{b}_{r}^{(e)} = (u,\psi_{q(e,r)}) = \int_{\Omega^{(e)}} u(x)\psi_{q(e,r)}(x)dx, \quad r = 0,1,\dots,d.$$

Using as before  $\psi_{q(e,r)}(x)=\ell_r(X)$  we get a mapping to the reference domain

$$ilde{b}_{r}^{(e)} = rac{h(e)}{2} \int_{-1}^{1} u(x(X)) \ell_{r}(X) dX, \quad r = 0, 1, \ldots, d.$$

#### Note

The vector  $m{ ilde{b}}^{(e)}$  needs to be assembled with an integral for each element because of u(x(X))

Assemble by adding up for all elements  $e=0,1,\dots,N_e-1$  and  $r=0,1,\dots,d$ 

$$b_{q(e,r)} \mathrel{+}= ilde{b}_r^{(e)}$$

#### Implementation $\boldsymbol{b}^{(e)}$

```
def map true domain(xj, e, d=1, x=x): # return x(X)
       xL, xR = get element boundaries(xi, e, d=d)
       hj = get_element_length(xj, e, d=d)
       return (xL+xR)/2+hj*x/2
   def map_reference_domain(xj, e, d=1, x=x): # return X(x)
       xL, xR = get_element_boundaries(xj, e, d=d)
       hj = get_element_length(xj, e, d=d)
       return (2*x-(xL+xR))/hi
   def map_u_true_domain(u, xj, e, d=1, x=x): # return u(x(X))
       return u.subs(x, map_true_domain(xj, e, d=d, x=x))
   def assemble_b(u, xj, d=1):
      l = Lagrangebasis(np.linspace(-1, 1, d+1), sympy=False)
       N = len(xj) - 1
       Ne = N//d
       b = np_z zeros(N+1)
19
       for elem in range(Ne):
20
           hj = get element length(xj, elem, d=d)
21
           us = sp.lambdify(x, map_u_true_domain(u, xj, elem, d=d))
22
           integ = lambda xj, r: us(xj)*l[r](xj)
23
           for r in range(d+1):
24
               b[local\_to\_global\_map(elem, r, d)] += hj/2*quad(integ, -1, 1, args=(r,))[0]
       return b
```

#### Note

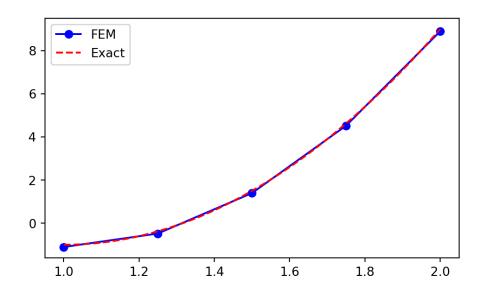

We need to perform an integral by calling  $\operatorname{\mathsf{quad}}$  for each r in each element.

#### **Example:** $u(x) = 10(x-1)^2 - 1, x \in [1,2]$

Use the previously implemented assemble\_mass and assemble\_b to find the approximation of u(x) using piecewise linear functions and FEM:

```
def assemble(u, N, domain=(-1, 1), d=1, xj=None):
    mesh = np.linspace(domain[0], domain[1], N+1)
    A = assemble_mass(mesh, d=d)
    b = assemble_b(u, mesh, d=d)
    return A, b

N = 4
xj = np.linspace(1, 2, N+1)
A, b = assemble(10*(x-1)**2-1, N, d=1, xj=xj)
uh = np.linalg.inv(A) @ b
yj = np.linspace(1, 2, 1000)
plt.figure(figsize=(6, 3.5))
plt.plot(xj, uh, 'b-o', yj, 10*(yj-1)**2-1, 'r--')
plt.legend(['FEM', 'Exact']);
```

#### i Note

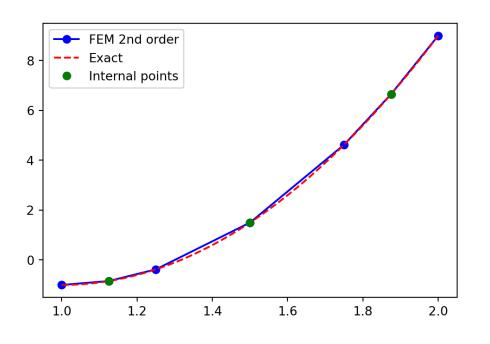

- Since we are using piecewise linear polynomials we can simply plot  $uh = (u_N(x_i))_{i=0}^N = (\hat{u}_i)_{i=0}^N$  and matplotlib will correctly fill in a linear profile between the points.
- The FEM solution  $u_N(x_i) 
  eq u(x_i)$

#### Second order (d=2)

Check that a non-uniform mesh works as well:

$$x_{2i} = 1 + (\cos(2\pi i/N) + 1)/2 \quad ext{and} \quad x_{2i+1} = rac{x_{2i} + x_{2(i+1)}}{2}$$

```
1 N = 6
2 xj = np.zeros(N+1)
3 xj[::2] = 1 + (np.cos(np.arange(N//2+1)*np.pi*2/N)
4 xj[1::2] = 0.5*(xj[:-1:2]+xj[2::2])
5 A, b = assemble(10*(x-1)**2-1, N, d=2, xj=xj)
6 uh = np.linalg.inv(A) @ b
7 yj = np.linspace(1, 2, 1000)
8 plt.figure(figsize=(6, 4))
9 plt.plot(xj, uh, '-bo', yj, 10*(yj-1)**2-1, 'r--')
10 plt.plot(xj[1::2], uh[1::2], 'go')
11 plt.legend(['FEM 2nd order', 'Exact', 'Internal po')
```

Why still linear interpolation? We need to use the higher order  $u_N(x)=\sum_{j=0}^N \hat{u}_j\psi_j(x)$  between mesh points! o FEM evaluation

#### Finite element evaluation

The finite element solution differs from the finite difference solution in that the solution is automatically defined everywhere within the domain.

$$u_N(x) = \sum_{j=0}^N \hat{u}_j \psi_j(x)$$

However, most basis functions will be zero at any location x. We need to find which element x belongs to! And then evaluate only with non-zero basisfunctions

$$u_N(x) = \sum_{r=0}^d \hat{u}_{q(e,r)} \ell_r(X), \quad x \in \Omega^{(e)}$$

```
def fe_evaluate(uh, p, xj, d=1):
    l = Lagrangebasis(np.linspace(-1, 1, d+1), sympy=False)
    elem = max(0, np.argmax(p <= xj[::d])-1) # find element containing p
    Xx = map_reference_domain(xj, elem, d=d, x=p)
    return Lagrangefunction(uh[d*elem:d*(elem+1)+1], l)(Xx)

fe_evaluate(uh, 1.2, xj, d=2), 10*(1.2-1)**2-1</pre>
```

#### Evaluate FEM for $N_d$ points

$$u_N(x_i) = \sum_{r=0}^d \hat{u}_{q(e,r)} \ell_r(X(x_i)), \quad x \in \Omega^{(e)}, \quad i = 0, 1, \dots, N_d - 1$$

Just loop over scalar code for each point

```
def fe_evaluate_v(uh, pv, xj, d=1):
    uj = np.zeros(len(pv))
    for i, p in enumerate(pv):
        uj[i] = fe_evaluate(uh, p, xj, d)
```

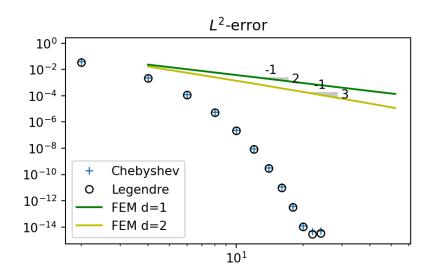

Alternatively, use vectorization, but not really straightforward:

```
def fe_evaluate_v(uh, pv, xj, d=1):
    l = Lagrangebasis(np.linspace(-1, 1, d+1), sympy=False)
    # Find points inside elements
    elem = (np.argmax((pv <= xj[::d, None]), axis=0)-1).clip(min=0)
    xL = xj[:-1:d] # All left element boundaries
    xR = xj[d::d] # All right element boundaries
    xm = (xL+xR)/2 # middle of all elements
    hj = (xR-xL) # length of all elements
    xx = 2*(pv-xm[elem])/hj[elem] # map pv to reference space all elements
    dofs = np.array([uh[e*d+np.arange(d+1)] for e in elem], dtype=float)
    V = np.array([lr(Xx) for lr in l], dtype=float) # All basis functions evaluated for all points
    return np.sum(dofs * V.T, axis=1)</pre>
```

#### More difficult example: $u(x) = e^{\cos x}$

Compute  $L^2(\Omega)$  error and compare with **global** Chebyshev and Legendre methods

```
def L2_error(uh, ue, xj, d=1):
       vi = np.linspace(-1, 1, 4*len(xj))
      uhj = fe_evaluate_v(uh, yj, xj, d=d)
       uei = ue(vi)
       return np.sgrt(np.trapz((uhj-uej)**2, dx=yj[1])
   u = sp.exp(sp.cos(x))
   ue = sp.lambdify(x, u)
 9 \, \text{err} = []
10 \text{ err2} = []
   for n in range(2, 30, 4):
       N = 2*n
13
       xj = np.linspace(-1, 1, N+1)
       A, b = assemble(u, N, (-1, 1), 1)
14
15
       uh = np.linalg.inv(A) @ b
       A2, b2 = assemble(u, N, (-1, 1), 2)
16
17
       uh2 = np.linalg.inv(A2) @ b2
18
       err.append(L2_error(uh, ue, xj, 1))
19
       err2.append(L2 error(uh2, ue, xj, 2))
```

#### Note

This illustrates nicely **spectral** versus **finite order** accuracy. With d=1 the FEM obtains second order accuracy and the error disappears as the linear (in the loglog-plot) green curve with slope -2 (from error  $\sim N^{-2}$ ). The spectral error on the other hand disappears exponentially as  $\sim e^{-\mu N}$ , faster than **any** finite order.

- Finite element software
- Developed originally at Chalmers University of Technology and UiO
- Very flexible and easy to use
- Solves PDEs with many different finite elements, including Lagrange

### For installation: https://github.com/FEniCS/dolfinx Anaconda

```
1 conda create -c conda-forge --name fenics fenics-dolfinx mpich pyvista
```

#### Linux

```
1 sudo add-apt-repository ppa:fenics-packages/fenics
2 sudo apt update
3 sudo apt install fenicsx
```

#### Docker

```
1 docker run -ti dolfinx/dolfinx:stable
```

# First example - function approximation using piecewise linear Lagrange elements

```
from mpi4py import MPI
from dolfinx import mesh, fem, cpp
from dolfinx.fem.petsc import LinearProblem
import ufl
from ufl import dx, inner

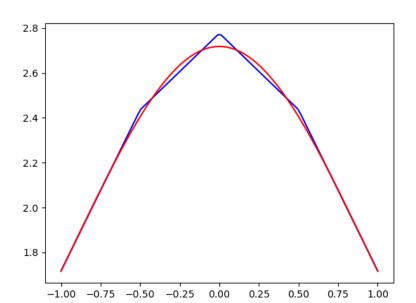

msh = mesh.create_interval(MPI.COMM_SELF, 4, (-1, 1))
v = fem.functionspace(msh, ("Lagrange", 1))
u = ufl.TrialFunction(V)
v = ufl.TestFunction(V)
xp = ufl.SpatialCoordinate(msh)
ue = ufl.exp(ufl.cos(xp[0]))
a = inner(u, v) * dx
L = inner(ue, v) * dx
problem = LinearProblem(a, L)
uh = problem.solve()
```

#### Alternatively assemble and solve linear problem yourself:

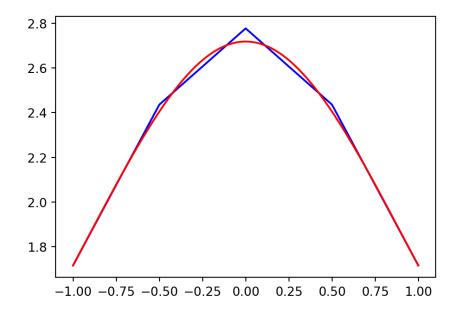

```
1 from scipy.sparse.linalg import spsolve
2 A = fem.assemble_matrix(fem.form(a))
3 b = fem.assemble_vector(fem.form(L))
4 uh = fem.Function(V)
5 uh.x.array[:] = spsolve(A.to_scipy(), b.array)
```

# Result 4 piecewise linear basis functions FEniCS Our implementation

```
1 N = 100
2 xj = np.zeros((N, 3))
3 xj[:, 0] = np.linspace(-1, 1, N)
4 data = cpp.geometry.determine_point_ownership(msh.
5 plt.plot(xj[:, 0], uh.eval(xj, data.dest_cells), '
6 plt.plot(xj[:, 0], sp.lambdify(x, sp.exp(sp.cos(x)))
```

# 1 N = 4 2 A1, b1 = assemble(u, N, (-1, 1), 1) 3 uN = np.linalg.inv(A1) @ b1 4 plt.figure(figsize=(5.5, 3.8)) 5 plt.plot(np.linspace(-1, 1, N+1), uN, 'b') 6 xj = np.linspace(-1, 1, 100) 7 plt.plot(xj, sp.lambdify(x, u)(xj), 'r')

#### Exactly the same result for the same method

FEniCS uses exactly the same method with piecewise linear basis functions as we have described using Sympy/Numpy and as such we get exactly the same matrix/vectors:

#### **FEniCS**

```
1 A.to_dense()
array([[0.1667, 0.0833, 0. , 0. , 0. ],
       [0.0833, 0.3333, 0.0833, 0. ],
       [0. , 0.0833, 0.3333, 0.0833, 0. ],
       [0. , 0. , 0.0833, 0.3333, 0.0833],
       [0. , 0. , 0.0833, 0.1667]])

1 b.array
array([0.4892, 1.1865, 1.3317, 1.1865, 0.4892])

1 uh.x.array
array([1.7169, 2.4361, 2.7772, 2.4361, 1.7169])
```

#### Sympy/Numpy

#### Summary

- The finite element method (FEM) is a variational method using **local** basis functions.
- The FEM uses the same Galerkin method as the methods using global basis functions.
- The FEM is assembled by running over all elements and assembling **local** matrices and vectors that are subsequently added to **global** matrices and vectors.
- Since all assembly work is performed elementwise, the FEM is very well suited for **unstructured** meshes.
